

Introduction

Providing quality education is a concern for any new college program. With the game programming degree being so new, there is going to be gaps in knowledge and blind spots that the program’s founders missed. That’s where I come in.

My job as an intern for the CIT department is to ensure that current and future students receive quality education in game programming. To do this, I have been taking a full scale approach on how I can help improve the program. This includes:

- Gathering student feedback for improvement
- Opening channels for communication
- Providing Student Support
- Creating marketing materials for the program
- Extending the program’s knowledge

Gathering Student Feedback

To get an idea on what support students needed, I prepared a list of common talking points in game programming (see below). The feedback was clear; students want help using software and writing code.

2. What Support would you like to see for the course? (Select all that apply)

Opening Communication Channels

I have been developing a Microsoft Team to compile all student resources. The Team also gives students the ability to discuss topics with each other. Most of all, this Team provides students with various documentation on game programming.

Providing Student Support

Through my time as a peer tutor and helping students outside of class, I’ve been helping students achieve academic success.

Students often come for help when their game stops working. I help them work through the problem and how they can prevent it in the future.

Creating Marketing Materials

Part of offering quality education is marketing what the program offers. As a result, I’ve spent plenty of time creating marketing materials for the program. This includes:

- Posters of many sizes
- Brochures

Extending Program Knowledge

Since the beginning of this semester, I’ve been developing a video game. The original goal for the game was to be used as direct marketing for the program. However, it is now also being used to extend the program’s knowledge on game programming.

The video game explores multiplayer and networking, something that has not been included in course curriculum. Additionally, the game will be published on the biggest video game platform, Steam.

Once the game is finished, I will be providing the program with complete documentation on networking concepts, topology, and how to get started with multiplayer video games as well as how to start building video games for Steam. By the end, I will have further extended the program’s knowledge and capabilities.
